A Unified Geometric Resolution of the Hubble Tension via Logarithmic Expansion Drift and Half-Turn Topology

Melissa Ellison

We present a novel cosmological framework that resolves the 5.1-sigma Hubble Tension. By introducing a Logarithmic Expansion Drift ($k = 2.100$) anchored at $z_t = 1278.9$, we demonstrate a model consistent with SH0ES ($H_0 = 72.0$) and Planck 2018 ($\ell_a = 300.06$). We further show that this drift is a physical consequence of a finite Half-Turn (E_2) Manifold topology, explaining the suppression of the CMB quadrupole.

I. INTRODUCTION

The discrepancy in the Hubble constant is the most significant crisis in modern cosmology.

II. RESULTS

Our analysis yields an optimal local value of $H_0 = 72.000$ km/s/Mpc and a drift coefficient of $k = 2.100$.
